Chapter 1

Overview of Features

Before using tabularray package, it is better to know how to typeset simple text and math tables with traditional tabular, tabularx and array environments, because we will compare tblr environment from tabularray package with these environments. You may read web pages on LaTeX tables on LearnLaTeX and Overleaf first.

1.1 Vertical Space

After loading tabularray package in the preamble, we can use tblr environments to typeset tabulars and arrays. The name tblr is short for tabularray or top-bottom-left-right. The following is our first example:

```
\begin{tabular}{lccr}
\hline
          & Beta & Gamma & Delta \\
Alpha
                                                           Alpha
                                                                      Beta
                                                                              Gamma
                                                                                        Delta
\hline
                                                           \overline{\mathrm{Epsilon}}
                             & Theta \\
                                                                      Zeta
                                                                                Eta
                                                                                        Theta
Epsilon & Zeta & Eta
                                                                              Lambda
\hline
                                                           Iota
                                                                     Kappa
                                                                                          Mu
Iota
          & Kappa & Lambda & Mu
\hline
\end{tabular}
```

```
\begin{tblr}{lccr}
\hline
Alpha
         & Beta & Gamma & Delta \\
                                                       Alpha
                                                                Beta
                                                                        Gamma
                                                                                 Delta
\hline
                                                                Zeta
                                                                          Eta
                                                                                 Theta
                                                       Epsilon
Epsilon & Zeta & Eta
                          & Theta \\
\hline
                                                       Iota
                                                               Kappa
                                                                       Lambda
                                                                                   Mu
Iota
         & Kappa & Lambda & Mu
                                   //
\hline
\end{tblr}
```

You may notice that there is extra space above and below the table rows with tblr environment. This space makes the table look better. If you don't like it, you could use \SetTblrInner command:

```
\SetTblrInner{rowsep=0pt}
\begin{tblr}{lccr}
\hline
 Alpha
         & Beta & Gamma & Delta \\
                                                       Alpha
                                                                Beta
                                                                        Gamma
                                                                                 Delta
\hline
                                                                                 Theta
                                                                Zeta
                                                                         Eta
                                                       Epsilon
 Epsilon & Zeta & Eta
                          & Theta \\
                                                       Iota
                                                               Kappa
                                                                        Lambda
                                                                                   Mu
\hline
 Iota
         & Kappa & Lambda & Mu
                                   11
\hline
\end{tblr}
```

But in many cases, this rowsep is useful:

```
$\begin{array}{rrr}
\hline
\dfrac{2}{3} & \dfrac{2}{3} & \dfrac{1}{3} \\
\dfrac{2}{3} & -\dfrac{1}{3} & -\dfrac{2}{3} \\
\dfrac{1}{3} & -\dfrac{2}{3} \\
\dfrac{1}{3} & -\dfrac{2}{3} \\
\dfrac{1}{3} & -\dfrac{2}{3} \\
\hline
\end{array}$
```

```
$\begin{tblr}{rrr}
                                                                                                                       1
\hline
                                                                                                                \overline{3}
                                                                                                        \overline{3}
                                                                                                                       \overline{3}
 \frac{2}{3} & \frac{2}{3} & \frac{2}{3} & \frac{1}{3} 
                                                                                                        2
                                                                                                                       2
                                                                                                                1
 \frac{2}{3} \& -\frac{1}{3} \& -\frac{2}{3} \
                                                                                                                       3
                                                                                                        \overline{3}
                                                                                                                \overline{3}
 \dfrac{1}{3} \& -\dfrac{2}{3} \& \dfrac{2}{3} \
                                                                                                        1
                                                                                                                       2
\hline
                                                                                                        \overline{3}
                                                                                                                \overline{3}
                                                                                                                       3
\end{tblr}$
```

Note that you can use tblr in both text and math modes.

1.2 Multiline Cells

It's quite easy to write multiline cells without fixing the column width in tblr environments: just enclose the cell text with braces and use \\ to break lines:

```
\begin{tblr}{|l|c|r|}
                                                                                            Center
                                                                                                       Right
                                                                                     Left
\hline
                                                                                             Cent
                                                                                                           \mathbf{R}
Left & {Center \\ Cent \\ C} & {Right \\ R} \\
                                                                                               \mathbf{C}
\hline
                                                                                     \mathbf{L}
                                                                                               \mathbf{C}
                                                                                                           \mathbf{R}
 {L \\ Left} & {C \\ Cent \\ Center} & R \\
                                                                                     Left
                                                                                              Cent
\hline
                                                                                            Center
\end{tblr}
```

1.3 Cell Alignment

From time to time, you may want to specify the horizontal and vertical alignment of cells at the same time. Tabularray package provides a Q column for this (In fact, Q column is the only primitive column, other columns are defined as Q columns with some options):

Note that you can use more meaningful t instead of p for top baseline alignment. For some users who are familiar with word processors, these t and b columns are counter-intuitive. In tabularray package, there are another two column types h and f, which will align cell text at the head and the foot, respectively:

```
\hline
       {\tt row} \& {\tt top} \& {\tt middle} & {\tt line} & {\tt row} & 
\hline
       {row}  & {top}  & {11}\22\mid\44\55}  & {line}  & {row}\foot}  \\
\hline
 \end{tblr}
                                                                                                                                                                                                                                                                line
       row
       head
                                                                                           top
                                                                                                                                                                               middle
                                                                                                                                                                                                                                                                bottom
                                                                                                                                                                                                                                                                                                                                                   row
                                                                                           line
                                                                                                                                                                                                                                                                                                                                                   foot
        row
                                                                                                                                                                               11
                                                                                                                                                                               22
       head
                                                                                                                                                                                                                                                                line
                                                                                                                                                                                                                                                                bottom
                                                                                           top
                                                                                                                                                                              mid
                                                                                          line
                                                                                                                                                                              44
                                                                                                                                                                                                                                                                                                                                                   row
                                                                                                                                                                              55
                                                                                                                                                                                                                                                                                                                                                   foot
```

1.4 Multirow Cells

The above **h** and **f** alignments are necessary when we write multirow cells with **\SetCell** command in tabularray.

```
\begin{tabular}{|1|1|1|1|}
\hline
\multirow[t]{4}{1.5cm}{Multirow Cell One} & Alpha &
\multirow[b]{4}{1.5cm}{Multirow Cell Two} & Alpha \\
& Beta & & Beta \\
& Gamma & & Gamma \\
& Delta & & Delta \\
\hline
\end{tabular}
            Alpha
                                Alpha
 Multirow
 Cell One
            Beta
                                Beta
            Gamma
                     Multirow
                                Gamma
           Delta
                     Cell Two
                                Delta
```

```
\begin{tblr}{|1|1|1|}
\hline
 \SetCell[r=4]{h,1.5cm} Multirow Cell One & Alpha &
 \ensuremath{\mbox{SetCell[r=4]\{f,1.5cm\}}} Multirow Cell Two & Alpha \\
 & Beta & & Beta \\
& Gamma & & Gamma \\
& Delta & & Delta \\
\hline
\end{tblr}
 Multirow
            Alpha
                                  Alpha
 Cell One
            Beta
                                  Beta
                                  Gamma
            Gamma
                      Multirow
            Delta
                                  Delta
                      Cell Two
```

Note that you don't need to load multirow package first, since tabularray doesn't depend on it. Furthermore, tabularray will always typeset decent multirow cells. First, it will set correct vertical middle alignment, even though some rows have large height:

```
\begin{tabular}{||1|m{4em}||}
                                                                                Alpha
\hline
\multirow[c]{4}{1.5cm}{Multirow} & Alpha \\
                                                                                Beta
                                                                     Multirow
& Beta \\
                                                                                Gamma
                                                                                Delta
& Gamma \\
                                                                                Delta
& Delta Delta \\
                                                                                Delta
\hline
\end{tabular}
\left| \left| \frac{4em}{1} \right| \right|
                                                                                Alpha
\hline
                                                                                Beta
\SetCell[r=4]{m,1.5cm} Multirow & Alpha \\
& Beta \\
                                                                                Gamma
                                                                     Multirow
& Gamma \\
                                                                                Delta
& Delta Delta \\
                                                                                Delta
\hline
                                                                                Delta
\end{tblr}
```

Second, it will enlarge row heights if the multirow cells have large height, therefore it always avoids vertical overflow:

```
\begin{tblr}{|l|m{4em}|}
\hline
\SetCell[r=2]{m,1cm} {Line \\ Line \\ Lin
```

If you want to distribute extra vertical space evenly to two rows, you may use **vspan** option described in Chapter 3.

1.5 Multi Rows and Columns

It was a hard job to typeset cells with multiple rows and multiple columns. For example:

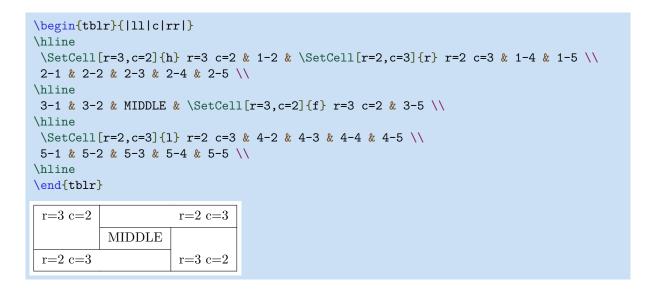

```
\begin{tabular}{|c|c|c|c|}
\hline
& \multicolumn{2}{c|}{2 Columns}
                & \multicolumn{2}{c|}{\multirow{2}{*}}{2 Rows 2 Columns}} \\
\left(2-3\right)
    & 2-2 & 2-3 & \multicolumn{2}{c|}{} \\
\hline
3-1 & 3-2 & 3-3 & 3-4 & 3-5 \\
\hline
\end{tabular}
         2 Columns
 2 Rows
                    2 Rows 2 Columns
         2-2
              2-3
         3-2
              3-3
                    3-4
                             3-5
  3-1
```

With tabularray package, you can set spanned cells with SetCell command: within the optional argument of SetCell command, option r is for rowspan number, and c for colspan number; within the mandatory argument of it, horizontal and vertical alignment options are accepted. Therefore it's much simpler to typeset spanned cells:

```
\begin{tblr}{|c|c|c|c|}
\hline
 \SetCell[r=2]{c} 2 Rows
     & \SetCell[c=2]{c} 2 Columns
                 & \SetCell[r=2,c=2]{c} 2 Rows 2 Columns & \\
\hline
                              11
     & 2-2 & 2-3 &
                        &
\hline
 3-1 & 3-2 & 3-3 & 3-4 & 3-5 \\
\hline
\end{tblr}
          2 Columns
 2 Rows
                      2 Rows 2 Columns
          2-2
                2-3
   3-1
          3-2
                3-3
                      3-4
                               3-5
```

Using \multicolumn command, the omitted cells must be removed. On the contrary, using \multirow command, the omitted cells must not be removed. \SetCell command behaves the same as \multirow command in this aspect.

With tblr environment, any \hline segments inside a spanned cell will be ignored, therefore we're free to use \hline in the above example. Also, any omitted cell will definitely be ignored when typesetting, no matter it's empty or not. With this feature, we could put row and column numbers into the omitted cells, which will help us to locate cells when the tables are rather complex:

1.6 Column Types

Tabularray package supports all normal column types, as well as the extendable X column type, which first occurred in tabularx package and was largely improved by tabu package:

Also, X columns with negative coefficients are possible:

```
\begin{tblr}{|X[2,1]|X[3,1]|X[-1,r]|X[r]|}
\hline
  Alpha & Beta & Gamma & Delta \\
\hline
\end{tblr}
Alpha

Beta

Gamma

Delta
```

We need the width to typeset a table with X columns. If unset, the default is \l To change the width, we have to first put all column specifications into $colspec=\{...\}$:

```
\begin{tblr}{width=0.8\linewidth,colspec={|X[2,1]|X[3,1]|X[-1,r]|X[r]|}}
\hline
Alpha & Beta & Gamma & Delta \\
\hline
\end{tblr}
Alpha
Beta
Gamma
Delta
```

You can define new column types with $\ensuremath{\tt NewColumnType}$ command. For example, in tabularray package, b and X columns are defined as special Q columns:

```
\NewColumnType{b}[1] {Q[b,wd=#1]}
\NewColumnType{X}[1][] {Q[co=1,#1]}
```

1.7 Row Types

Now that we have column types and colspec option, you may ask for row types and rowspec option. Yes, they are here:

```
{Alpha \\ Alpha} & Beta
                             & Gamma \\
Delta
             & Epsilon
                             & {Zeta \\ Zeta} \\
Eta
             & {Theta \\ Theta}
                             & Iota \\
\end{tblr}
Alpha
       Beta
            Gamma
Alpha
               Zeta
Delta
      Epsilon
               Zeta
      Theta
Eta
      Theta
               Iota
```

Same as column types, Q is the only primitive row type, and other row types are defined as Q types with different options. It's better to specify horizontal alignment in colspec, and vertical alignment in rowspec, respectively.

Inside rowspec, | is the hline type. Therefore we need not to write \hline command, which makes table code cleaner.

1.8 Hlines and Vlines

Hlines and vlines have been improved too. You can specify the widths and styles of them:

```
\begin{tblr}{||| [dotted] | [2pt] c|r | [solid] | [dashed] |}
\hline
One
      & Two & Three \\
                                                                                  Three
                                                                  One
                                                                           Two
\hline\hline[dotted]\hline
Four & Five & Six \\
                                                                  Four
                                                                           Five
                                                                                    Six
\hline[dashed]\hline[1pt]
                                                                  Seven
                                                                          Eight
                                                                                   Nine
Seven & Eight & Nine \\
\hline
\end{tblr}
```

1.9 Colorful Tables

To add colors to your tables, you need to load xcolor package first. Tabularray package will also load ninecolors package for proper color contrast. First you can specify background option for Q rows/columns inside rowspec/colspec:

```
\begin{tblr}{colspec={lcr},rowspec={|Q[cyan7]|Q[azure7]|Q[blue7]|}}
        & Beta & Gamma \\
Alpha
Epsilon & Zeta & Eta
Iota
        & Kappa & Lambda \\
\end{tblr}
 Alpha
          Beta
                 Gamma
Epsilon
          Zeta
                     Eta
         Kappa
                 Lambda
 Iota
```

```
\begin{tblr}{colspec={Q[1,brown7]Q[c,yellow7]Q[r,olive7]},rowspec={|Q|Q|Q|}}
Alpha & Beta & Gamma \\
Epsilon & Zeta & Eta \\
Iota & Kappa & Lambda \\
end{tblr}
Alpha Beta Gamma
Epsilon Zeta Eta
Iota Kappa Lambda
```

Also you can use \SetRow or \SetColumn command to specify row or column colors:

```
\begin{tblr}{colspec={lcr},rowspec={|Q|Q|Q|}}
\SetRow{cyan7} Alpha & Beta & Gamma \\
\SetRow{azure7} Epsilon & Zeta & Eta \\
\SetRow{blue7} Iota & Kappa & Lambda \\
\end{tblr}
Alpha Beta Gamma
Epsilon Zeta Eta
Iota Kappa Lambda
```

```
\begin{tblr}{colspec={lcr},rowspec={|Q|Q|Q|}}
\SetColumn{brown7}
               & \SetColumn{yellow7}
Alpha
                                                           Alpha
                                                                    Beta
                                                                            Gamma
                                 & \SetColumn{olive7}
                 Beta
                                                           Epsilon
                                                                    Zeta
                                                                               Eta
                                   Gamma \\
                                                           Iota
                                                                    Kappa
                                                                           Lambda
                                 & Eta \\
               & Zeta
Epsilon
Iota
               & Kappa
                                 & Lambda \\
\end{tblr}
```

Hlines and vlines can also have colors:

```
begin{tblr}{colspec={lcr},rowspec={|[2pt,green7]Q|[teal7]Q|[green7]Q|[3pt,teal7]}}
Alpha & Beta & Gamma \\
Epsilon & Zeta & Eta \\
Iota & Kappa & Lambda \\
end{tblr}
Alpha Beta Gamma
Epsilon Zeta Eta
Iota Kappa Lambda
```

```
\begin{tblr}{colspec={|[2pt,violet5]1|[2pt,magenta5]c|[2pt,purple5]r|[2pt,red5]}}
Alpha
        & Beta & Gamma \\
Epsilon & Zeta & Eta
        & Kappa & Lambda \\
Iota
\end{tblr}
 Alpha
          Beta
                  Gamma
 Epsilon
          Zeta
                     Eta
 Iota
          Kappa
                  Lambda
```

Chapter 2

Basic Interfaces

2.1 Old and New Interfaces

With tabularray package, you can change the styles of tables via old interfaces or new interfaces.

The old interfaces consist of some table commands inside the table contents. Same as tabular and array environments, all table commands must be put at the beginning of the cell text. Also, new table commands must be defined with \NewTableCommand.

The new interfaces consist of some options inside the mandatory argument, hence totally separating the styles and the contents of tables.

Table 2.1: Old Interfaces and New Interfaces

Old Interfaces	New Interfaces
\SetHlines	hlines
\SetHline, \hline, \hborder, \cline	hline, hborder, rowspec
\SetVlines	vlines
\SetVline, \vline, \vborder, \rline	vline, vborder, colspec
\SetCells	cells
\SetCell	cell
\SetRows	rows
\SetRow	row, rowspec
\SetColumns	columns
\SetColumn	column, colspec

2.2 Hlines and Vlines

All available keys for hlines and vlines are described in Table 2.2 and Table 2.3.

Table 2.2: Keys for Hlines

Key	Description and Values	Initial Value
dash	dash style: solid, dashed or dotted	solid
text	replace hline with text (like! specifier in rowspec)	×
<u>wd</u>	rule width dimension	0.4pt

Continued on next page

Table 2.2: Keys for Hlines (Continued)

Key	Description and Values	Initial Value
<u>fg</u>	rule color name	×
leftpos	crossing or trimming position at the left side	1
rightpos	crossing or trimming position at the right side	1
endpos	adjust leftpos/rightpos for only the leftmost/rightmost column	false

Note: In most cases, you can omit the underlined key names and write only their values.

Table 2.3: Keys for Vlines

Key	Description and Values	Initial Value
dash	dash style: solid, dashed or dotted	solid
text	replace vline with text (like! specifier in colspec)	×
<u>wd</u>	rule width dimension	0.4pt
<u>fg</u>	rule color name	×
abovepos	crossing or trimming position at the above side	0
belowpos	crossing or trimming position at the below side	0

Note: In most cases, you can omit the underlined key names and write only their values.

2.2.1 Hlines and Vlines in New Interfaces

Options hlines and vlines are for setting all hlines and vlines, respectively. With empty value, all hlines/vlines will be solid.

```
\begin{tblr}{hlines, vlines}
                                                       Alpha
                                                                Beta
                                                                        Gamma
                                                                                 Delta
         & Beta & Gamma
                            & Delta
                                      11
Epsilon & Zeta & Eta
                                                       Epsilon
                                                                Zeta
                                                                        Eta
                                                                                  Theta
                            & Theta
                                      11
         & Kappa & Lambda & Mu
                                      11
Iota
                                                       Iota
                                                                        Lambda
                                                                                 Mu
                                                                Kappa
\end{tblr}
```

With values inside one pair of braces, all hlines/vlines will be styled.

```
\begin{tblr}{
hlines = {1pt,solid}, vlines = {red3,dashed},
                                                       Alpha
                                                                Beta
                                                                        Gamma
                                                                                 Delta
         & Beta & Gamma
                                                                Zeta
                                                                                 Theta
                                                       Epsilon
                                                                        Eta
Alpha
                            & Delta
                                      11
Epsilon & Zeta & Eta
                            & Theta
                                      11
                                                      Iota
                                                                Kappa
                                                                        Lambda
                                                                                 Mu
         & Kappa & Lambda & Mu
                                      11
\end{tblr}
```

Another pair of braces before will select segments in all hlines/vlines.

```
\begin{tblr}{
vlines = \{1,3,5\}\{dashed\},
                                                       Alpha
                                                                Beta
                                                                         Gamma
                                                                                   Delta
vlines = \{2,4\}\{\text{solid}\},
                                                       Epsilon
                                                                Zeta
                                                                         Eta
                                                                                   Theta
         & Beta & Gamma
Alpha
                             & Delta
                                        //
                                                                Kappa
                                                                         Lambda
                                                                                   Mu
                                                       Iota
Epsilon & Zeta & Eta
                             & Theta
                                        //
                                                       Nu
                                                                Xi
                                                                         Omicron
                                                                                   Ρi
         & Kappa & Lambda
                            & Mu
                                        //
Nu
         & Xi
                & Omicron & Pi
                                        11
                                                       Rho
                                                                Sigma
                                                                         Tau
                                                                                   Upsilon
Rho
         & Sigma & Tau
                             & Upsilon \\
\end{tblr}
```

The above example can be simplified with odd and even values. (More child selectors can be defined with \NewChildSelector command. Advanced users could read the source code for this.)

```
\begin{tblr}{
vlines = {odd}{dashed},
                                                     Alpha
                                                              Beta
                                                                       Gamma
                                                                                 Delta
vlines = {even}{solid},
                                                                       Eta
                                                                                 Theta
                                                     Epsilon
                                                              Zeta
         & Beta & Gamma
Alpha
                            & Delta
                                       11
                                                     Iota
                                                              Kappa
                                                                       Lambda
                                                                                 Mu
Epsilon & Zeta & Eta
                            & Theta
                                       11
                                                              Xi
                                                                                 Ρi
                                                     Nu
                                                                       Omicron

                                                      Nu
                                                               Χi
                                                                       Omicron
 Iota
         & Kappa & Lambda & Mu
                                       //
                                                      Rho
                                                                       Tau
                                                                                 Upsilon
                                                               Sigma
 Nu
         & Xi
                 & Omicron & Pi
                                                      Phi
                                                               Chi
                                                                       Psi
                                                                                 Omega
 Rho
         & Sigma & Tau
                            & Upsilon \\
 Phi
         & Chi
                 & Psi
                            & Omega
\end{tblr}
```

You can use U, V, W, X, Y, Z to denote the last six children, respectively. It is especially useful when you are writing long tables:

```
\begin{tblr}{
 hline{1,Z} = {2pt},
 hline{2,Y} = {1pt},
                                                      Alpha
                                                               Beta
                                                                       Gamma
                                                                                 Delta
 hline{3-X} = {dashed},
                                                      Epsilon
                                                               Zeta
                                                                       Eta
                                                                                  Theta
}
                                                      Iota
                                                               Kappa
                                                                       Lambda
                                                                                 Mu
         & Beta & Gamma
                                       11
 Alpha
                            & Delta
 Epsilon & Zeta & Eta
                            & Theta

                                                      Nu
                                                               Xi
                                                                        Omicron
                                                                                 Ρi
 Iota
         & Kappa & Lambda & Mu
                                       11
                                                      Rho
                                                               Sigma
                                                                       Tau
                                                                                  Upsilon
         & Xi
                 & Omicron & Pi
 Nu
                                       11
                                                      Phi
                                                               Chi
                                                                       Psi
                                                                                  Omega
 Rho
         & Sigma & Tau
                            & Upsilon \\
 Phi
         & Chi
                 & Psi
                            & Omega
\end{tblr}
```

Now we show the usage of text key by the following example¹:

```
\begin{tblr}{
  vlines, hlines,
  colspec = {lX[c]X[c]X[c]X[c]},
  vline{2} = {1}{text=\clap{:}},
  vline{3} = {1}{text=\clap{\ch{+}}},
  vline{4} = {1}{text=\clap{\ch{->}}},
  vline{5} = {1}{text=\clap{\ch{+}}},
  Equation & \ch{CH4} & \ch{2 02} & \ch{C02} & \ch{2 H20} \\
  Initial & $n_1$
                        & $n_2$
                                     & O
                                              & 0 \\
  Final
            & $n_1-x$ & $n_2-2x$ & $x$
                                                  & $2x$ \\
\end{tblr}
 Equation:
                   CH_4
                                        2O_2
                                                             CO_2
                                                                                 2\,\mathrm{H}_2\mathrm{O}
 Initial
                                                              0
                                                                                   0
                    n_1
                                         n_2
 Final
                                                                                   2x
                  n_1 - x
                                       n_2 - 2x
                                                              \boldsymbol{x}
```

You need to load chemmacros package for the \ch command.

The leftpos and rightpos keys specify crossing or trimming positions for hlines. The possible values for them are decimal numbers between -1 and 1. Their initial values are 1.

-1	the hline is trimmed by colsep
0	the hline only touches the first vline
1	the hline touches all the vlines

The abovepos and belowpos keys for vlines have similar meanings. But their initial values are 0.

-1	the vline is trimmed by rowsep
0	the vline only touches the first hline
1	the vline touches all the hlines

Here is an example for these four keys:

```
\begin{tblr}{
 hline{1,4} = {1}{-}{},
 hline{1,4} = {2}{-}{},
 hline{2,3} = {1}{-}{leftpos = -1, rightpos = -1},
                                                             Alpha
                                                                      Beta
                                                                              Gamma
 hline{2,3} = {2}{-}{leftpos = -1, rightpos = -1},
  vline{1,4} = {abovepos = 1, belowpos = 1},
                                                             Epsilon
                                                                      Zeta
                                                                              Eta
                                                                              Lambda
                                                             Iota
                                                                      Kappa
         & Beta & Gamma
Alpha
 Epsilon & Zeta & Eta
                          11
         & Kappa & Lambda \\
 Iota
\end{tblr}
```

There is also an endpos option for adjusting leftpos/rightpos for only the leftmost/rightmost column:

 $^{^{1}\}mathrm{Code\ from\ https://tex.stackexchange.com/questions/603023/tabularray-and-tabularx-column-separator.}$

```
\begin{tblr}{
hline{1,4} = {1}{-}{},
hline{1,4} = {2}{-}{},
hline{2,3} = {leftpos = -1, rightpos = -1, endpos},
                                                             Alpha
                                                                      Beta
                                                                              Gamma
vline{1,4} = {abovepos = 1, belowpos = 1},
                                                                      Zeta
                                                             Epsilon
                                                                              Eta
                                                             Iota
                                                                      Kappa
                                                                              Lambda
        & Beta & Gamma \\

        & Kappa & Lambda \\
\end{tblr}
```

2.2.2 Hlines and Vlines in Old Interfaces

The \hline command has an optional argument which accepts key-value options. The available keys are described in Table 2.2.

```
\begin{tblr}{llll}
\hline
Alpha
         & Beta & Gamma & Delta \\
                                                      Alpha
                                                               Beta
                                                                       Gamma
                                                                                 Delta
\hline[dashed]
                                                      Epsilon
                                                               Zeta
                                                                       Eta
                                                                                 Theta
Epsilon & Zeta & Eta
                          & Theta \\
\hline[dotted]
                                                      Iota
                                                                       Lambda
                                                                                 Mu
                                                               Kappa
Iota
         & Kappa & Lambda & Mu
                                   11
\hline[2pt,blue5]
\end{tblr}
```

The \cline command also has an optional argument which is the same as \hline.

```
\begin{tblr}{llll}
\left(1-4\right)
Alpha
         & Beta & Gamma & Delta \\
                                                       Alpha
                                                                Beta
                                                                        Gamma
                                                                                  Delta
\cline[dashed] {1,3}
                                                                        Eta
                                                                                  Theta
                                                       Epsilon
                                                                Zeta
Epsilon & Zeta & Eta
                           & Theta \\
\cline[dashed]{2,4}
                                                                        Lambda
                                                                                 Mu
                                                       Iota
                                                                Kappa
Iota
         & Kappa & Lambda & Mu
                                   //
\cline[2pt,blue5]{-}
\end{tblr}
```

You can use child selectors in the mandatory argument of \cline.

```
\begin{tblr}{llll}
\left(1-4\right)
         & Beta & Gamma & Delta \\
Alpha
                                                                         Gamma
                                                                                  Delta
                                                       Alpha
                                                                Beta
\cline[dashed] {odd}
                                                       Epsilon
                                                                 Zeta
                                                                         Eta
                                                                                  Theta
Epsilon & Zeta & Eta
                           & Theta \\
\cline[dashed] {even}
                                                       Iota
                                                                Kappa
                                                                         Lambda
                                                                                  Mu
Iota
         & Kappa & Lambda & Mu
                                   11
\cline[2pt,blue5]{-}
\end{tblr}
```

Commands \SetHline combines the usages of \hline and \cline:

```
\begin{tblr}{llll}
\SetHline{1-3}{blue5,1pt}
                                                             Beta
                                                                     Gamma
                                                                              Delta
                                                     Alpha
Alpha
        & Beta & Gamma & Delta \\
                                                                              Theta
Epsilon & Zeta & Eta & Theta \\
                                                     Epsilon
                                                             Zeta
                                                                     Eta
        & Kappa & Lambda & Mu
                                                     Iota
                                                             Kappa
                                                                     Lambda
                                                                              Mu
\SetHline{2-4}{teal5,1pt}
\end{tblr}
\begin{tblr}{llll}
\SetHline[1]{1-3}{blue5,1pt}
\SetHline[2]{1-3}{azure5,1pt}
                                                     Alpha
                                                             Beta
                                                                     Gamma
                                                                              Delta
Alpha & Beta & Gamma & Delta \\
                                                     Epsilon
Epsilon & Zeta & Eta & Theta \\
                                                             Zeta
                                                                     Eta
                                                                              Theta
        & Kappa & Lambda & Mu
                                                                              Mu
                                                     Iota.
                                                             Kappa
                                                                     Lambda
SetHline[1]{2-4}{teal5,1pt}
\SetHline[2]{2-4}{green5,1pt}
```

In fact, table command \SetHline[<index>]{<styles>} at the beginning of row i is the same as table option hline{i}={<index>}{<styles>}.

Also, table command \SetHlines[<index>]{<columns>}{<styles>} at the beginning of some row is the same as table option hlines={<index>}{<columns>}{<styles>}.

The usages of table commands \vline, \rline, \SetVline, \SetVlines are similar to those of \hline, \cline, \SetHlines, \respectively. But normally you don't need to use them.

2.3 Hborders and Vborders

\end{tblr}

Options hborder{i} and vborder{j} are similar to hline{i} and vline{j}, respectively, but they hold border specifications not related to one specific hline and vline. All available keys for hborder{i} and vborder{j} are described in Table 2.4 and Table 2.5.

Key	Description and Values	Initial Value
pagebreak	pagebreak at this position: yes, no or auto (See Chapter 4)	auto
abovespace	set belowsep of previous row (see Table 2.8)	2pt
belowspace	set abovesep of current row (see Table 2.8)	2pt
abovespace+	increase belowsep of previous row	×
belowspace+	increase abovesep of current row	×

Table 2.4: Keys for Hborders

Table 2.5: Keys for Vborders

Key	Description and Values	Initial Value
leftspace	set rightsep of previous column (see Table 2.9)	6pt
rightspace	set leftsep of current column (see Table 2.9)	6pt
leftspace+	increase rightsep of previous column	×
rightspace+	increase leftsep of current column	×

Furthermore, table command \hborder{<specs>} at the beginning of row i is the same as table option hborder{i}={<specs>}, and table command \vborder{<specs>} at the beginning of column j is the same as table option vborder{j}={<specs>}.

2.4 Cells and Spancells

All available keys for cells are described in Table 2.6 and Table 2.7.

Table 2.6: Keys for the Content of Cells

Key	Description and Values	Initial Value
halign	horizontal alignment: 1 (left), c (center), r (right) or j (justify)	j
valign	vertical alignment: t (top), m (middle), b (bottom), h (head) or f (foot)	t
<u>wd</u>	width dimension	×
<u>bg</u>	background color name	×
fg	foreground color name	×
font	font commands	×
mode	set cell mode: math, imath, dmath or text	×
\$	same as mode=math	×
\$\$	same as mode=dmath	×
cmd	execute command for the cell text	×
preto	prepend text to the cell	×
appto	append text to the cell	×

Note: In most cases, you can omit the underlined key names and write only their values.

Table 2.7: Keys for Multispan of Cells

Key	Description and Values	Initial Value
r	number of rows the cell spans	1
С	number of columns the cell spans	1

2.4.1 Cells and Spancells in New Interfaces

Option cells is for setting all cells.

```
\begin{tblr}{hlines={white},cells={c,blue7}}
                                                                     Gamma
                                                     Alpha
                                                              Beta
                                                                              Delta
Alpha & Beta & Gamma & Delta
                                    11
                                                    Epsilon
                                                              Zeta
                                                                       Eta
                                                                              Theta
Epsilon & Zeta & Eta

2.4.2 Cells and Spancells in Old Interfaces

The \SetCell command has a mandatory argument for setting the styles of current cell. The available keys are described in Table 2.6.

```
\begin{tblr}{llll}
\hline[1pt]
         & \SetCell{bg=teal2,fg=white} Beta & Gamma \\
Alpha
                                                              Alpha
                                                                       Beta
                                                                               Gamma
\hline
Epsilon & Zeta & \SetCell{r,font=\scshape} Eta \\
                                                              Epsilon
                                                                       Zeta
                                                                                  Ета
\hline
                                                              Iota
                                                                               Lambda
                                                                       Kappa
         & Kappa & Lambda \\
Iota
\hline[1pt]
\end{tblr}
```

The \SetCell command also has an optional argument for setting the multispan of current cell. The available keys are described in Table 2.7.

```
\begin{tblr}{|X|X|X|X|X|X|}
\hline
 Alpha & Beta
                 & Gamma
                           & Delta & Epsilon & Zeta \\
\hline
 \SetCell[r=2]{m} Eta
       & Theta
                & Iota
                           & Kappa & Lambda & \SetCell[r=2]{m} Mu \\

                                    & Rho
                                              & Sigma \\
\hline
\end{tblr}
               Beta
                              Gamma
                                            Delta
                                                           Epsilon
                                                                          Zeta
 Alpha
               Theta
                                                           Lambda
                              Iota
                                            Kappa
 Eta
                                                                          Mu
               Χi
                              Omicron
                                            Ρi
                                                           Rho
```

In fact, table command $\ensuremath{\sc i} ={\ensuremath{\sc i}} = \ensuremath{\sc i} = \ens$

Also, table command \SetCells[]{<styles>} at the beginning of some cell is the same as table option cells={}{<styles>}.

2.5 Rows and Columns

All available keys for rows and columns are described in Table 2.8 and Table 2.9.

Key **Description and Values Initial Value** horizontal alignment: 1 (left), c (center), r (right) or j (justify) halign j vertical alignment: t (top), m (middle), b (bottom), h (head) or f (foot) valign ht height dimension background color name bg foreground color name fg font font commands set mode for row cells: math, imath, dmath or text mode \$ same as mode=math X \$\$ same as mode=dmath \times execute command for every cell text cmd abovesep set vertical space above the row 2pt increase vertical space above the row abovesep+ × set vertical space below the row belowsep 2pt belowsep+ increase vertical space below the row X set vertical space above and below the row rowsep 2pt rowsep+ increase vertical space above and below the row prepend text to every cell (like > specifier in rowspec) preto append text to every cell (like < specifier in rowspec) appto

Table 2.8: Keys for Rows

Note: In most cases, you can omit the underlined key names and write only their values.

Table 2.9: Keys for Columns

Key	Description and Values	Initial Value
halign	horizontal alignment: 1 (left), c (center), r (right) or j (justify)	j
<u>valign</u>	vertical alignment: t (top), m (middle), b (bottom), h (head) or f (foot)	t
<u>wd</u>	width dimension	×
<u>co</u>	coefficient for the extendable column (X column)	×
bg	background color name	×
fg	foreground color name	×
font	font commands	×
mode	set mode for column cells: math, imath, dmath or text	×
\$	same as mode=math	×
\$\$	same as mode=dmath	×
cmd	execute command for every cell text	×
leftsep	set horizontal space to the left of the column	6pt
leftsep+	increase horizontal space to the left of the column	×
rightsep	set horizontal space to the right of the column	6pt
rightsep+	increase horizontal space to the right of the column	×
colsep	set horizontal space to both sides of the column	6pt
colsep+	increase horizontal space to both sides of the column	X
preto	prepend text to every cell (like > specifier in colspec)	×
appto	append text to every cell (like < specifier in colspec)	×

Note: In most cases, you can omit the underlined key names and write only their values.

2.5.1 Rows and Columns in New Interfaces

Options rows and columns are for setting all rows and columns, respectively.

```
\begin{tblr}{

                Epsilon
Delta
                              Zeta
 Eta
                Theta
                              Iota
                              Mu
 Kappa
                Lambda
 Nu Xi Omicron
                Pi Rho Sigma
                              Tau Upsilon Phi
```

The following example demonstrates the usages of mode key:

```
$\begin{tblr}{
  column{1} = {mode=text},
  column{3} = {mode=dmath},
                                                                                    Alpha
                                                                                                  \frac{\overline{2}}{3}
\hline
                                                                                    Epsilon
  Alpha & \frac12 & \frac12 \\
  Epsilon & \frac34 & \frac34 \\
                                                                                                  5
                                                                                    Iota
           & \frac56 & \frac56 \\
                                                                                                  \overline{6}
  Iota
\hline
\end{tblr}$
```

The following example demonstrates the usages of abovesep, belowsep, leftsep, rightsep keys:

```
\begin{tblr}{
hlines, vlines,
rows = {abovesep=1pt,belowsep=5pt},
                                                         Alpha
                                                                 Beta
                                                                       Gamma Delta
columns = {leftsep=1pt,rightsep=5pt},
                                                         Epsilon
                                                                Zeta
                                                                       Eta
                                                                                Theta
        & Beta & Gamma & Delta \\
Alpha
                                                                 Kappa
                                                                       Lambda
                                                                               Mu
                                                         Iota
Epsilon & Zeta & Eta
                          & Theta \\
         & Kappa & Lambda & Mu
\end{tblr}
```

The following example shows that we can replace \\[dimen] with belowsep+ key.

```
\begin{tblr}{
hlines, row{2} = {belowsep+=5pt},
                                                      Alpha
                                                              Beta
                                                                      Gamma
                                                                                Delta
}
                                                      Epsilon
                                                              Zeta
                                                                      Eta
                                                                                Theta
         & Beta & Gamma & Delta \\
 Epsilon & Zeta & Eta
                         & Theta \\
                                                      Iota
                                                                      Lambda
                                                                                Mu
                                                              Kappa
 Iota
         & Kappa & Lambda & Mu
\end{tblr}
```

2.5.2 Rows and Columns in Old Interfaces

The \SetRow command has a mandatory argument for setting the styles of current row. The available keys are described in Table 2.8.

```
\begin{tblr}{llll}
\hline[1pt]
\SetRow{azure8} Alpha & Beta & Gamma & Delta \\
                                                      Alpha
                                                               Beta
                                                                       Gamma
                                                                                 Delta
                                                                Zeta
                                                                         Eta
\SetRow{blue8,c} Epsilon & Zeta & Eta & Theta \\
                                                      Epsilon
                                                                                 Theta
                                                      Iota
                                                               Kappa
                                                                       Lambda
                                                                                 Mu
\SetRow{violet8} Iota & Kappa & Lambda & Mu \\
\hline[1pt]
\end{tblr}
```

In fact, table command $\ensuremath{\tt SetRow{<styles>}}$ at the beginning of row i is the same as table option $row{i}={<styles>}$.

Also, table command \SetRows{<styles>} at the beginning of some row is the same as table option rows={<styles>}.

The usages of table commands \SetColumn and \SetColumns are similar to those of \SetRow and \SetRows, respectively. But normally you don't need to use them.

2.6 Colspec and Rowspec

Options colspec/rowspec are for setting column/row specifications with column/row type specifiers.

2.6.1 Colspec and Width

Option width is for setting the width of the table with extendable columns. The following example demonstrates the usage of width option.

```
& Beta & Gamma & Delta \\
Epsilon & Zeta & Eta & Theta \\
Iota
      & Kappa & Lambda & Mu
\end{tblr}
Alpha
      Beta
                     Gamma
                                           Delta
Epsilon
      Zeta
                     Eta
                                           Theta
      Kappa
                     Lambda
                                           Mu
```

You can omit colspec name if it is the only key you use inside the mandatory argument. The following example demonstrates the usages of \$ and \$\$ keys:

```
\begin{tblr}{Q[1]Q[r,$]Q[r,$$]}
\hline
                                                                                      Alpha
                                                                                                     \bar{2}
  Alpha
          & \frac12 & \frac12 \\
                                                                                                     3
  Epsilon & \frac34 & \frac34 \\
                                                                                     Epsilon
                                                                                                    \overline{4}
           & \frac56 & \frac56 \\
                                                                                                    5
\hline
                                                                                      Iota
                                                                                                    \overline{6}
\end{tblr}
```

2.6.2 Column Types

The tabularray package has only one type of primitive column: the Q column. Other types of columns are defined as Q columns with some keys.

```
\NewColumnType{1}{Q[1]}
\NewColumnType{c}{Q[c]}
\NewColumnType{r}{Q[r]}
\NewColumnType{t}[1]{Q[t,wd=#1]}
\NewColumnType{m}[1]{Q[m,wd=#1]}
\NewColumnType{b}[1]{Q[b,wd=#1]}
\NewColumnType{h}[1]{Q[h,wd=#1]}
\NewColumnType{f}[1]{Q[f,wd=#1]}
\NewColumnType{f}[1]{Q[f,wd=#1]}
\NewColumnType{X}[1][]{Q[co=1,#1]}
```

```
Gamma
\begin{tblr}{|t{15mm}|m{15mm}|b{20mm}|}
                                                    Alpha
                                                               Beta
                                                                         Gamma
        & Beta & {Gamma\\Gamma} \\
Alpha
                                                                         Eta
Epsilon & Zeta & {Eta\\Eta} \\
                                                    Epsilon
                                                               Zeta
                                                                         Eta
Iota
        & Kappa & {Lambda\\Lambda} \\
                                                                         Lambda
\end{tblr}
                                                    Iota
                                                               Kappa
                                                                         Lambda
```

Any new column type must be defined with **\NewColumnType** command. It can have an optional argument when it's defined.

2.6.3 Row Types

The tabularray package has only one type of primitive row: the Q row. Other types of rows are defined as Q rows with some keys.

```
\NewRowType{1}{Q[1]}
\NewRowType{c}{Q[c]}
\NewRowType{r}{Q[r]}
\NewRowType{t}[1]{Q[t,ht=#1]}
\NewRowType{m}[1]{Q[m,ht=#1]}
\NewRowType{b}[1]{Q[b,ht=#1]}
\NewRowType{h}[1]{Q[h,ht=#1]}
\NewRowType{f}[1]{Q[h,ht=#1]}
```

```
Alpha
                                                                  Beta
                                                                         Gamma
                                                                         Gamma
\label{local_begin_tblr} $$ \operatorname{lt}_{10mm} | m_{10mm} | b_{10mm} | $$ $$
Alpha & Beta & {Gamma\\Gamma} \\
                                                                         Eta
Epsilon & Zeta & {Eta\\Eta} \\
                                                                  Zeta
                                                          Epsilon
                                                                         Eta
\end{tblr}
                                                                         Lambda
                                                          Iota
                                                                  Kappa
                                                                         Lambda
```

Any new row type must be defined with \NewRowType command. It can have an optional argument when it's defined.

Chapter 3

Extra Interfaces

In general, tblr environment can accepts both inner and outer specifications:

```
\begin{tblr}[<outer specs>]{<inner specs>}

    \end{tblr}
```

Inner specifications are all specifications written in the <u>mandatory</u> argument of tblr environment, which include new interfaces described in Chapter 2.

Outer specifications are all specifications written in the <u>optional</u> argument of tblr environment, most of which are used for long tables (see Chapter 4).

You can use \SetTblrInner and \SetTblrOuter commands to set default inner and outer specifications of tables, respectively (see Section 3.3).

3.1 Inner Specifications

In addition to new interfaces in Chapter 2, there are several inner specifications which are described in Table 3.1.

Table 3.1: Keys for Inner Specifications

Key	Description and Values	Initial Value
rulesep	space between two hlines or vlines	2pt
stretch	stretch ratio for struts added to cell text	1
abovesep	set vertical space above every row	2pt
belowsep	set vertical space below every row	2pt
rowsep	set vertical space above and below every row	2pt
leftsep	set horizontal space to the left of every column	6pt
rightsep	set horizontal space to the right of every column	6pt
colsep	set horizontal space to both sides of every column	6pt
hspan	horizontal span algorithm: default, even, or minimal	default
vspan	vertical span algorithm: default or even	default
baseline	set the baseline of the table	m

3.1.1 Space between Double Rules

The following example shows that we can replace \doublerulesep parameter with rulesep key.

```
\begin{tblr}{
 colspec={||llll||},rowspec={|QQQ|},rulesep=4pt,
                                                                    Gamma
                                                    Alpha
                                                            Beta
                                                                             Delta
                                                            Zeta
                                                                    Eta
                                                                             Theta
        & Beta & Gamma & Delta \\
                                                    Epsilon
 Alpha
 Epsilon & Zeta & Eta
                         & Theta \\
                                                    Iota
                                                            Kappa
                                                                    Lambda
                                                                             Mu
        & Kappa & Lambda & Mu
\end{tblr}
```

3.1.2 Minimal Strut for Cell Text

The following example shows that we can replace \arraystretch parameter with stretch key.

```
\begin{tblr}{hlines,stretch=1.5}
                                                                      Gamma
                                                                               Delta
                                                     Alpha
                                                              Beta
        & Beta & Gamma & Delta \\
Alpha
Epsilon & Zeta & Eta
                         & Theta \\
                                                     Epsilon
                                                              Zeta
                                                                      Eta
                                                                               Theta
Iota
        & Kappa & Lambda & Mu
                                                     Iota
\end{tblr}
                                                              Kappa
                                                                     Lambda
                                                                               Mu
```

By replacing stretch with row heights, we can get perfect vertical centering for your numerical tables.

```
\begin{tblr}{hlines, stretch=0, rows={ht=\baselineskip}} 2021 & 2022 & 2023 \\
0.4 & 0.5 & 0.6 \\
1.1 & 2.2 & 3.3 \\
end{tblr}
```

3.1.3 Rowseps and Colseps for All

The following example uses rowsep and colsep keys to set padding for all rows and columns.

```
\SetTblrInner{rowsep=2pt,colsep=2pt}
\begin{tblr}{hlines,vlines}
Alpha & Beta & Gamma & Delta \\
Epsilon & Zeta & Eta & Theta \\
Iota & Kappa & Lambda & Mu \\
\end{tblr}
\lambda & Mu \\
```

3.1.4 Hspan and Vspan Algorithms

With hspan=default or hspan=even, tabularray package will compute column widths from span widths. But with hspan=minimal, it will compute span widths from column widths. The following examples show the results from different hspan values.

```
\SetTblrInner{hlines, vlines, hspan=default}
\begin{tblr}{cell{2}{1}={c=2}{1},cell{3}{1}={c=3}{1},cell{4}{2}={c=2}{1}}

111 111 & 222 222 & 333 333 \\

12 Multi Columns Multi Columns 12 & & 333 \\

13 Multi Columns Multi Columns Multi Columns 13 & & \\
\end{tblr}

111 111 222 222 333 333 \\

12 Multi Columns Multi Columns 12 333 \\

13 Multi Columns Multi Columns 12 333 \\

13 Multi Columns Multi Columns Multi Columns 13 \\

111 23 Multi Columns Multi Columns 23
```

```
\SetTblrInner{hlines, vlines, hspan=minimal}
\begin{tblr}{cell{2}{1}={c=2}{1},cell{3}{1}={c=3}{1},cell{4}{2}={c=2}{1}}
111 111 & 222 222 & 333 333 \\
12 Multi Columns Multi Columns 12 & & 333 \\
13 Multi Columns Multi Columns Multi Columns 13 & & \\
111 & 23 Multi Columns Multi Columns 23 & \\
\end{tblr}
 111 111
        222 222
                  333 333
 12 Multi Columns
                   333
 Multi Columns 12
 13 Multi Columns Multi
 Columns Multi Columns 13
          23 Multi Columns
 111
          Multi Columns 23
```

The following examples show the results from different vspan values.

```
\SetTblrInner{hlines, vlines, vspan=default}
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Column1
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         Column2

                                Row4 & Short text \\
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Row4
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Short text
  \end{tblr}
```

3.1.5 Use Verbatim Commands

The inner key verb is obsolete from version 2023A, and will be removed in the future. Instead you can use more reliable \fakeverb command (see Section 6.2).

3.1.6 Set Baseline for the Table

With baseline key, you can set baseline for the table. All possible values for baseline are as follows:

t	align the table at the top
T	align the table at the first row
m	align the table at the middle, initial value
b	align the table at the bottom
В	align the table at the last row
<n></n>	align the table at row <n> (a positive integer)</n>

If there is no hline above the first row, you get the same result with either t or T. But you get different results if there are one or more hlines above the row:

```
Baseline\begin{tblr}{hlines,baseline=t}
                                              Baseline
                                                                               Baseline
                                                      Alpha
                                                               Beta
                                                                       Gamma
 Alpha & Beta & Gamma
 Epsilon & Zeta & Eta
                                                      Epsilon
                                                               Zeta
                                                                       Eta
         & Kappa & Lambda \\
                                                      Iota
                                                                       Lambda
                                                               Kappa
\end{tblr}Baseline
```

<pre>Baseline\begin{tblr}{hlines,baseline=T} Alpha & Beta & Gamma \\</pre>	Baseline	Alpha	Beta	Gamma	Baseline
Epsilon & Zeta & Eta \\		Epsilon	Zeta	Eta	
<pre>Iota & Kappa & Lambda \\ \end{tblr}Baseline</pre>	-	Iota	Kappa	Lambda	-

The differences between b and B are similar to t and T. In fact, these two values T and B are better replacements for currently obsolete \firsthline and \lasthline commands.

3.2 Outer Specifications

Except for specifications to be introduced in Chapter 4, there are several other outer specifications which are described in Table 3.2.

KeyDescription and ValuesInitial Valuebaselineset the baseline of the tablemlongchange the table to a long table×tallchange the table to a tall table×expandyou need this key to use verb commands×

Table 3.2: Keys for Outer Specifications

3.2.1 Set Baseline in Another Way

You may notice that you can write baseline option as either an inner or an outer specification. It is true that either way would do the job. But there is a small difference: when baseline=t/T/m/b/B is an outer specification, you can omit the key name and write the value only.

```
Baseline\begin{tblr}[m]{hlines}
                                                        Alpha
                                                                Beta
                                                                        Gamma
 Alpha
         & Beta & Gamma
 Epsilon & Zeta & Eta
                                               Baseline Epsilon
                                                                Zeta
                                                                        Eta
                                                                                 Baseline
                           11
         & Kappa & Lambda \\
 Iota
                                                        Iota
                                                                Kappa
                                                                        Lambda
\end{tblr}Baseline
```

3.2.2 Long and Tall Tables

You can change a table to long table by passing outer specification long, or change it to tall table by passing outer specification tall (see Chapter 4). Therefore the following two tables are the same:

```
\begin{longtblr}{lcr}
Alpha & Beta & Gamma
\end{longtblr}
\begin{tblr}[long]{lcr}
Alpha & Beta & Gamma
\end{tblr}
```

3.2.3 Expand Macros First

In contrast to traditional tabular environment, tabularray environments need to see every & and \\ when splitting the table body with l3regex. And you can not put cell text inside any table command defined with \NewTableCommand. But you could use outer key expand to make tabularray expand every occurrence of a specified macro once before splitting the table body. Note that you can not expand a command defined with \NewDocumentCommand.

To expand a command without optional argument, you can define it with \newcommand.

```
\newcommand*\tblrbody{
\hline
 20 & 30 & 40 \\
                                                                          AA
                                                                                BB
                                                                                     CC
 50 & 60 & 70 \\
 \hline
                                                                          20
                                                                                30
                                                                                     40
                                                                          50
                                                                                60
                                                                                     70
\begin{tblr}[expand=\tblrbody]{ccc}
                                                                          DD
                                                                                EE
                                                                                     FF
\hline
 AA & BB & CC \\
                                                                          20
                                                                                30
                                                                                     40
  \tblrbody
                                                                          50
                                                                                60
                                                                                     70
 DD & EE & FF \\
                                                                          GG
                                                                               HH
                                                                                     II
  \tblrbody
 GG & HH & II \\
 \hline
\end{tblr}
```

To expand commands with optional arguments, you <u>can not</u> define them with \newcommand. But you can define them with \NewExpandableDocumentCommand, and use option expand=\expanded to do exhaustive expansions.

```
\NewExpandableDocumentCommand\yes{O{Yes}m}{\SetCell{bg=green9}#1}
\NewExpandableDocumentCommand\no{O{No}m}{\SetCell{bg=red9}#1}
\begin{tblr}[expand=\expanded]{hlines}
  What I get
                          & is below
  \expanded{\yes{}}
                          & \expanded{\no{}}
                                                   11
  \expanded{\yes[Great]{}} & \expanded{\no[Bad]{}}
\end{tblr}
 What I get
            is below
 Yes
            No
            Bad
 Great
```

Note that you need to protect fragile commands (if any) inside them with \unexpanded command.

3.3 Default Specifications

Tabularray package provides \SetTblrInner and \SetTblrOuter commands for you to change the default inner and outer specifications of tables.

In general different tabularray environments (tblr, talltblr, longtblr, etc) could have different default specifications. You can list the environments in the optional arguments of these two commands, and they only apply to tblr environment when the optional arguments are omitted.

In the following example, the first line draws all hlines and vlines for all tblr tables created afterwards, while the second line makes all tblr tables created afterwards vertically align at the last row.

```
\SetTblrInner{hlines,vlines}
\SetTblrOuter{baseline=B}
```

And the following example sets zero rowsep for all tblr and longtblr tables created afterwards.

```
\SetTblrInner[tblr,longtblr]{rowsep=0pt}
```

3.4 New Tabularray Environments

You can define new tabularray environments using \NewTblrEnviron command:

```
\NewTblrEnviron{mytblr}
\SetTblrInner[mytblr]{hlines, vlines}
\SetTblrOuter[mytblr]{baseline=B}
                                                                     \operatorname{Gamma}
                                                    Alpha
                                                             Beta
                                                                               Delta
Text \begin{mytblr}{cccc}
                                                              Zeta
                                                    Epsilon
                                                                       Eta
                                                                               Theta
         & Beta & Gamma & Delta \\
 Alpha
                                             Text
                                                     Iota
                                                                     Lambda
                                                                                Mu
                                                                                      Text
                                                            Kappa
 Epsilon & Zeta & Eta
                           & Theta \\
         & Kappa & Lambda & Mu
 Iota
\end{mytblr} Text
```

3.5 New General Environments

With +b argument type of \NewDocumentEnvironment command, you can also define a new general environment based on tblr environment (note that there is an extra pair of curly braces at the end):

```
\NewDocumentEnvironment{fancytblr}{+b}{
  Before Text
  \begin{tblr}{hlines}
    #1
  \end{tblr}
  After Text
}{}
\begin{fancytblr}
                                                        One
                                                               Two
                                                                      Three
  One & Two & Three \\

                                                                      Nine
\end{fancytblr}
```

3.6 New Table Commands

All commands which change the specifications of tables must be defined with \NewTableCommand. The following example demonstrates how to define a new table command:

```
\NewTableCommand\myhline{\hline[0.1em,red5]}
\begin{tblr}{llll}
\myhline
                                                    Alpha
                                                             Beta
                                                                     Gamma
                                                                              Delta
Alpha
        & Beta & Gamma
                          & Delta \\
                                                             Zeta
                                                                              Theta
                                                    Epsilon
                                                                     Eta
Epsilon & Zeta & Eta
                          & Theta \\
                                                    Iota
                                                             Kappa
                                                                    Lambda
                                                                              Mu
Iota
        & Kappa & Lambda & Mu
\myhline
\end{tblr}
```

3.7 Odd and Even Selectors

From version 2022A, child selectors odd and even accept an optional argument, in which you can specify the start index and the end index of the children.

```
\begin{tblr}{
  cell{odd}{1} = {red9},
                                                             Head
                                                                      Head
                                                                               Head
  cell{odd[4]}{2} = {green9},
                                                                      Place A
                                                                               Date A
  cell{odd[3-X]}{3} = {blue9},
                                                             Talk A
                                                             Talk B Place B
                                                                               Date B

                                                                               Date G
  Talk F & Place F & Date F \\
  Talk G & Place G & Date G \\
                                                                     Place H
                                                             Talk H
                                                                               Date H
  Talk H & Place H & Date H \\
\end{tblr}
```

3.8 Counters and Lengths

Counters rownum, colnum, rowcount, colcount can be used in cell text:

```
\begin{tblr}{hlines}
Cell[\arabic{rownum}] [\arabic{colnum}] & Cell[\arabic{rownum}] [\arabic{colnum}] &
Cell[\arabic{rownum}] [\arabic{colnum}] & Cell[\arabic{rownum}] [\arabic{colnum}] \/
Row=\arabic{rowcount}, Col=\arabic{colcount} &
Row=\arabic{rowcount}, Col=\arabic{colcount} &
Row=\arabic{rowcount}, Col=\arabic{colcount} &
Row=\arabic{rowcount}, Col=\arabic{colcount} \\
Cell[\arabic{rownum}][\arabic{colnum}] & Cell[\arabic{rownum}][\arabic{colnum}] &
Cell[\arabic{rownum}] [\arabic{colnum}] & Cell[\arabic{rownum}] [\arabic{colnum}] \\
\end{tblr}
                Cell[1][2]
Cell[1][1]
                                Cell[1][3]
                                                Cell[1][4]
Row=3, Col=4
                Row=3, Col=4
                                Row=3, Col=4
                                                Row=3, Col=4
 Cell[3][1]
                Cell[3][2]
                                Cell[3][3]
                                                Cell[3][4]
```

Also, lengths \leftsep, \rightsep, \abovesep, \belowsep can be used in cell text.

3.9 Tracing Tabularray

To trace internal data behind tblr environment, you can use \SetTblrTracing command. For example, \SetTblrTracing{all} will turn on all tracings, and \SetTblrTracing{none} will turn off all tracings. \SetTblrTracing{+row,+column} will only tracing row and column data. All tracing messages will be written to the log files.

Chapter 4

Use Long Tables

4.1 A Simple Example

To make a decent long table with header and footer, it is better to separate header/footer as table head/foot (which includes caption, footnotes, continuation text) and <u>row head/foot</u> (which includes some rows of the table that should appear in every page). By this approach, alternating row colors work as expected.

Table 4.1: A Long Long Long Long Long Long Table

Head	Head	Head
Head	Head	Head
Alpha	Beta	Gamma
Epsilon	Zeta ^a	Eta
Iota	Kappa [†]	Lambda
Nu	Xi	Omicron

^a It is the first footnote.

 $\it Note$: Some general note. Some general note.

Source: Made up by myself. Made up by myself. Made up by myself.

As you can see in the above example, the appearance of long tables of tabularray package is similar to that of threeparttablex packages. It supports table footnotes, but not page footnotes.

 $^{^{\}dagger}$ It is the second long long long long long long footnote.

The source code for the above long table is shown below. It is mainly self-explanatory.

```
\NewTblrTheme{fancy}{
  \SetTblrStyle{firsthead}{font=\bfseries}
  \SetTblrStyle{firstfoot}{fg=blue2}
  \SetTblrStyle{middlefoot}{\itshape}
  \SetTblrStyle{caption-tag}{red2}
\begin{longtblr}[

Foot
        & Foot & Foot
                         11
\hline
\end{longtblr}
```

As you can see in the above code, we typeset long tables with longtblr environment. And we can totally separate contents and styles of long tables with tabularray package.

Row head and row foot consist of some lines of the table and should appear in every page. Their options are inner specifications and should be put in the mandatory argument of the longtblr environment. In the above example, We set rowhead=2 and rowfoot=1.

Table 4.2: Inner Specifications for Row Heads and Row Foots

Key Name	Key Description	Initial Value
rowhead	number of the first rows of the table appear in every page	0
rowfoot	number of the last rows of the table appear in every page	0

Table head and table foot consist of the caption, continuation text, footnotes and remarks. Their options are outer specifications and should be put in the optional argument of the longtblr environment.

Table 4.3: Outer Specifications for Table Heads and Table Foots

Key Name	Key Description	Initial Value
headsep	vertical space between table head and table body	6pt
footsep	vertical space between table foot and table body	6pt
presep	vertical space between table head and the above text	1.5\bigskipamount
postsep	vertical space between table foot and the below text	1.5\bigskipamount
theme	table theme (including settings for templates and styles)	×
caption	table caption	×
entry	short table caption to be put in List of Tables	×
label	table label	×
note{ <name>}</name>	table note with <name> as tag</name>	×
remark{ <name>}</name>	table remark with <name> as tag</name>	×

If you write entry=none, tabularray package will not add an entry in List of Tables. Therefore caption=text,entry=none is similar to \caption[]{text} in longtable.

If you write label=none, tabularray package will not step table counter, and set the caption-tag and caption-sep elements (see below) to empty. Therefore caption=text,entry=none,label=none is similar to \caption*{text} in longtable, except for the counter.

4.2 Customize Templates

4.2.1 Overview of Templates

The template system for table heads and table foots in tabularray is largely inspired by beamer, caption and longtable packages. For elements in Table 4.4, you can use \DefTblrTemplate¹ to define and modify templates, and use \SetTblrTemplate to choose default templates. In defining templates, you can include other templates with \UseTblrTemplate and \ExpTblrTemplate commands.

 $^{^1\}mathrm{From}$ version 2022A, \DefTblrTemplate has another name \DeclareTblrTemplate.

Element Description and Default Template Element Name continuation text in the foot, normally "Continued on next page" contfoot-text continuation paragraph in the foot, normally including contfoot-text template contfoot continuation text in the head, normally "(Continued)" conthead-text conthead continuation paragraph in the head, normally including conthead-text template caption tag, normally like "Table 4.2" caption-tag caption separator, normally like ": caption-sep caption text, normally using user provided value caption-text including caption-tag + caption-sep + caption-textcaption note tag, normally using user provided value note-tag note separator, normally like " " note-sep note tag, normally using user provided value note-text note including note-tag + note-sep + note-textremark tag, normally using user provided value remark-tag remark separator, normally like ": " remark-sep remark-text remark text, normally using user provided value remark including remark-tag + remark-sep + remark-textfirsthead table head on the first page, normally including caption template middlehead table head on middle pages, normally including caption and conthead templates table head on the last page, normally including caption and conthead templates lasthead head setting all of firsthead, middlehead and lasthead firstfoot table foot on the first page, normally including contfoot template middlefoot table foot on middle pages, normally including contfoot template lastfoot table foot on the last page, normally including note and remark templates foot setting all of firstfoot, middlefoot and lastfoot

Table 4.4: Elements for Table Heads and Table Foots

An element which only includes short text is called a <u>sub element</u>. Normally there is one – in the name of a sub element. An element which includes one or more paragraphs is called a <u>main element</u>. Normally there isn't any – in the name of a main element.

For each of the above elements, two templates normal and empty are always defined. You can select one of them with \SetTblrTemplate command.

4.2.2 Continuation Templates

Let us have a look at the code for defining templates of continuation text first:²

```
\DefTblrTemplate{contfoot-text}{normal}{Continued on next page}
\SetTblrTemplate{contfoot-text}{normal}
\DefTblrTemplate{conthead-text}{normal}{(Continued)}
\SetTblrTemplate{conthead-text}{normal}
```

In the above code, command \DefTblrTemplate defines the templates with name normal, and then command \SetTblrTemplate sets the templates with name normal as default. The normal template is always defined and set as default for any element in tabularray. Therefore you had better use another name when defining new templates.

²To tell the truth, the default conthead-text and contfoot-text are actually stored in commands \tblrcontheadname and \tblrcontfootname respectively. And you may contribute your translations of them to babel package.

If you use default as template name in \DefTblrTemplate, you define and set it as default at the same time. Therefore the above code can be written in another way:

```
\DefTblrTemplate{contfoot-text}{default}{Continued on next page}
\DefTblrTemplate{conthead-text}{default}{(Continued)}
```

You may modify the code to customize continuation text to fit your needs.

The templates for contfoot and conthead normally include the templates of their sub elements with \UseTblrTemplate commands. But you can also handle user settings such as horizontal alignment here.

```
\DefTblrTemplate{contfoot}{default}{\UseTblrTemplate{contfoot-text}{default}} 
\DefTblrTemplate{conthead}{default}{\UseTblrTemplate{conthead-text}{default}}
```

4.2.3 Caption Templates

Normally a caption consists of three parts, and their templates are defined with the follow code:

```
\DefTblrTemplate{caption-tag}{default}{Table\hspace{0.25em}\thetable} \DefTblrTemplate{caption-sep}{default}{:\enskip} \DefTblrTemplate{caption-text}{default}{\InsertTblrText{caption}}
```

The command \InsertTblrText{caption} inserts the value of caption key, which you could write in the optional argument of longtblr environment.

The caption template normally includes three sub templates with \UseTblrTemplate commands: The caption template will be used in firsthead template.

```
\DefTblrTemplate{caption}{default}{
  \UseTblrTemplate{caption-tag}{default}
  \UseTblrTemplate{caption-sep}{default}
  \UseTblrTemplate{caption-text}{default}
}
```

Furthermore capcont template includes conthead template as well. The capcont template will be used in middlehead and lasthead templates.

```
\DefTblrTemplate{capcont}{default}{
  \UseTblrTemplate{caption-tag}{default}
  \UseTblrTemplate{caption-sep}{default}
  \UseTblrTemplate{caption-text}{default}
  \UseTblrTemplate{conthead-text}{default}
}
```

4.2.4 Note and Remark Templates

The templates for table notes can be defined like this:

```
\DefTblrTemplate{note-tag}{default}{\textsuperscript{\InsertTblrNoteTag}}
\DefTblrTemplate{note-sep}{default}{\space}
\DefTblrTemplate{note-text}{default}{\InsertTblrNoteText}
```

```
\DefTblrTemplate{note}{default}{
  \mapTblrNotes{
    \noindent
    \UseTblrTemplate{note-tag}{default}
    \UseTblrTemplate{note-sep}{default}
    \UseTblrTemplate{note-text}{default}
    \useTblrTemplate{note-text}{default}
    \upar
    }
}
```

The \MapTblrNotes command loops for all table notes, which are written in the optional argument of longtblr environment. Inside the loop, you can use \InsertTblrNoteTag and \InsertTblrNoteText commands to insert current note tag and note text, respectively.

The definition of remark templates are similar to note templates.

```
\DefTblrTemplate{remark-tag}{default}{\InsertTblrRemarkTag}
\DefTblrTemplate{remark-sep}{default}{:\space}
\DefTblrTemplate{remark-text}{default}{\InsertTblrRemarkText}
```

```
\DefTblrTemplate{remark}{default}{
  \MapTblrRemarks{
    \noindent
    \UseTblrTemplate{remark-tag}{default}
    \UseTblrTemplate{remark-sep}{default}
    \UseTblrTemplate{remark-text}{default}
    \par
  }
}
```

4.2.5 Head and Foot Templates

The templates for table heads and foots are defined as including other templates:

```
\DefTblrTemplate{firsthead}{default}

\UseTblrTemplate{middlehead,lasthead}{default}{
 \UseTblrTemplate{capcont}{default}}

\DefTblrTemplate{firstfoot,middlefoot}{default}{
 \UseTblrTemplate{contfoot}{default}}

\DefTblrTemplate{contfoot}{default}}

\UseTblrTemplate{lastfoot}{default}{
 \UseTblrTemplate{note}{default}}

\UseTblrTemplate{remark}{default}}

}
```

Note that you can define the same template for multiple elements in \DefTblrTemplate command. If you only want to show table caption in the first page, you may change the definitions of middlehead and lasthead elements:

```
\DefTblrTemplate{middlehead,lasthead}{default}{
  \UseTblrTemplate{conthead}{default}
}
```

4.3 Change Styles

All available keys for template elements are described in Table 4.5.

Table 4.5: Keys for the Styles of Elements

Key Name	Key Description	Initial Value
fg	foreground color	×
<u>font</u>	font commands	×
halign	horizontal alignment: 1 (left), $\tt c$ (center), $\tt r$ (right) or $\tt j$ (justify)	j
indent	parindent value	0pt
hang	hangindent value	Opt or 0.7em

Note: In most cases, you can omit the underlined key names and write only their values. The keys halign, indent and hang are only for main templates.

You may change the styles of elements with \SetTblrStyle command:

```
\SetTblrStyle{firsthead}{font=\bfseries}
\SetTblrStyle{firstfoot}{fg=blue2}
\SetTblrStyle{middlefoot}{\itshape}
\SetTblrStyle{caption-tag}{red2}
```

When you write \UseTblrTemplate{element}{default} in defining a template, beside including template code of the element, the foreground color and font commands of the element will be set up automatically. In contrast, \ExpTblrTemplate{element}{default} will only include template code.

4.4 Define Themes

You may define your own themes for table heads and foots with \NewTblrTheme command. a theme consists of some template and style settings. For example:

```
\NewTblrTheme{fancy}{
  \DefTblrTemplate{conthead}{default}{[Continued]}
  \SetTblrStyle{firsthead}{font=\bfseries}
  \SetTblrStyle{firstfoot}{fg=blue2}
  \SetTblrStyle{middlefoot}{\itshape}
  \SetTblrStyle{caption-tag}{red2}
}
```

After defining the theme fancy, you can use it by writing theme=fancy in the optional argument of longtblr environment.

4.5 Control Page Breaks

Just like longtable package, inside longtblr environment, you can use * or \nopagebreak to prohibit a page break, and use \pagebreak to force a page break.

4.6 Floatable Tall Tables

There is also a talltblr environment as an alternative to threeparttable environment. It can not cross multiple pages, but it can be put inside table environment.

```
TEXT\begin{talltblr}[
  caption = {Long Long Long Tabular},
  entry = {Short Caption},
  label = {tblr:tall},
 note{a} = {It is the first footnote.},
 note{\frac{1}{2}} = {It is the second long long long long long long footnote.},
]{
  colspec = {XXX}, width = 0.5\linewidth, hlines,
}
 Alpha & Beta & Gamma \\
  Epsilon & Zeta & Eta\TblrNote{a} \\
  \end{talltblr}TEXT
         Table 4.6: Long Long Long Long Tabular
       Alpha
                     Beta
                                    Gamma
       Epsilon
                     Zeta
                                    Eta<sup>a</sup>
TEXT.
                                                  TEXT
      Iota
                     Kappa
                                    Lambda<sup>†</sup>
     <sup>a</sup> It is the first footnote.
     <sup>†</sup> It is the second long long long long long long foot-
       note.
```

Use Some Libraries

The tabularray package emulates or fixes some commands in other packages. To avoid potential conflict, you need to enable them with \UseTblrLibrary command.

5.1 Library amsmath

With \UseTblrLibrary{amsmath} in the preamble of the document, tabularray will load amsmath package, and define +array, +matrix, +bmatrix, +Bmatrix, +pmatrix, +vmatrix, +Vmatrix and +cases environments. Each of the environments is similar to the environment without + prefix in its name, but has default rowsep=2pt just as tblr environment. Every environment except +array accepts an optional argument, where you can write inner specifications.

5.2 Library booktabs

With \UseTblrLibrary{booktabs} in the preamble of the document, tabularray will load booktabs package, and define \toprule, \midrule, \bottomrule and \cmidrule inside tblr environment.

```
\begin{tblr}{llll}
\toprule
Alpha
        & Beta & Gamma
                           & Delta \\
                                                      Alpha
                                                               Beta
                                                                       Gamma
                                                                                 Delta
\midrule
Epsilon & Zeta & Eta
                           & Theta \\
                                                      Epsilon
                                                               Zeta
                                                                       Eta
                                                                                 Theta
\cmidrule{1-3}
                                                      Iota
                                                               Kappa
                                                                       Lambda
                                                                                 Mu
         & Kappa & Lambda & Mu
Iota
                                                                                 Pi
                                                      Nu
                                                               Χi
\cmidrule{2-4}
                                                                       Omicron
Nu
        & Xi
                 & Omicron & Pi
                                    11
\bottomrule
\end{tblr}
```

Just like \hline and \cline commands, you can also specify rule width and color in the optional argument of any of these commands.

```
\begin{tblr}{llll}
\toprule[2pt,purple3]
Alpha
       & Beta & Gamma & Delta \\
                                                                        Gamma
                                                                                 Delta
                                                       Alpha
                                                               Beta
\midrule[blue3]
                                                       Epsilon
                                                               Zeta
                                                                        Eta
                                                                                 Theta
Epsilon & Zeta & Eta
                          & Theta \\
\cmidrule[azure3]{2-3}
                                                                       Lambda
                                                       Iota
                                                               Kappa
                                                                                 M_{11}
         & Kappa & Lambda & Mu
\bottomrule[2pt,purple3]
\end{tblr}
```

If you need more than one \cmidrules, you can use \cmidrulemore command.

```
\begin{tblr}{llll}
\toprule
Alpha & Beta & Gamma
                           & Delta \\
                                                              Beta
                                                                      Gamma
                                                                               Delta
                                                      Alpha
\cmidrule{1-3} \cmidrulemore{2-4}
                                                      Epsilon
                                                              Zeta
                                                                      Eta
                                                                                Theta
Epsilon & Zeta & Eta
                           & Theta \\
\cmidrule{1-3} \morecmidrules \cmidrule{2-4}
                                                      Iota
                                                                      Lambda
                                                                               Mu
                                                              Kappa
        & Kappa & Lambda & Mu
\bottomrule
\end{tblr}
```

From version 2021N (2021-09-01), trim options (1, r, lr) for \cmidrule command are also supported.

```
\begin{tblr}{llll}
\toprule
Alpha
         & Beta & Gamma
                           & Delta \\
                                                      Alpha
                                                               Beta
                                                                       Gamma
                                                                                Delta
\cmidrule[lr]{1-2} \cmidrule[lr=-0.4]{3-4}
                                                                                Theta
                                                      Epsilon
                                                               Zeta
                                                                       Eta
Epsilon & Zeta & Eta
                           & Theta \\
\cmidrule[r]{1-2} \cmidrule[1]{3-4}
                                                      Iota
                                                                                Mu
                                                               Kappa
                                                                       Lambda
Iota
         & Kappa & Lambda & Mu
\bottomrule
\end{tblr}
```

Note that you need to put 1, r or 1r option into the <u>square brackets</u>. and the possible values are decimal numbers between -1 and 0, where -1 means trimming the whole colsep, and 0 means no trimming. The default value is -0.8, which makes similar result as booktabs package does.

There is also a booktabs environment for you. With this environment, the default rowsep=0pt, but extra

vertical space will be added by \toprule, \midrule, \bottomrule and \cmidrule commands. The sizes of vertical space are determined by \aboverulesep and \belowrulesep dimensions.

```
\begin{booktabs}{
  colspec = lcccc,
  cell{1}{1} = {r=2}{}, cell{1}{2,4} = {c=2}{},
\toprule
                                                                                      II
                                                                              T
                                                                   Sample
  Sample & I & & II & \\
                                                                            A
                                                                               В
                                                                                    \mathbf{C}
                                                                                       D
\cmidrule[lr]{2-3} \cmidrule[lr]{4-5}
                                                                   S1
                                                                            5
                                                                                6
                                                                                    7
                                                                                        8
         & A & B & C & D \\
                                                                   S2
                                                                            6
                                                                                7
                                                                                    8
                                                                                        5
\midrule
                                                                            7
         & 5 & 6 & 7 & 8 \\
                                                                   S3
                                                                                8
                                                                                    5
                                                                                        6

  S2
         & 7 & 8 & 5 & 6 \\
  S3
\bottomrule
\end{booktabs}
```

You can also use \specialrule command. The second argument sets belowsep of previous row, and the third argument sets abovesep of current row,

```
\begin{booktabs}{row{2}={olive9}}
\toprule
         & Beta & Gamma
Alpha
                           & Delta \\
                                                                       Gamma
                                                      Alpha
                                                               Beta
                                                                                Delta
\specialrule{0.5pt}{4pt}{6pt}
Epsilon & Zeta & Eta
                           & Theta \\
                                                      Epsilon
                                                               Zeta
                                                                       Eta
                                                                                Theta
\specialrule{0.8pt,blue3}{3pt}{2pt}
                                                      Iota
                                                                       Lambda
                                                               Kappa
                                                                                Mu
Iota
         & Kappa & Lambda & Mu
\bottomrule
\end{booktabs}
```

At last, there is also an \addlinespace command. You can specify the size of vertical space to be added in its optional argument, and the default size is 0.5em. This command adds one half of the space to belowsep of previous row, and the other half to abovesep of current row.

```
\begin{booktabs}{row{2}={olive9}}
\toprule
Alpha
         & Beta & Gamma
                           & Delta \\
                                                      Alpha
                                                               Beta
                                                                       Gamma
                                                                                 Delta
\addlinespace
                                                      Epsilon
                                                               Zeta
                                                                       Eta
                                                                                 Theta
Epsilon & Zeta & Eta
                           & Theta \\
\addlinespace[1em]
                                                      Iota
                                                                       Lambda
                                                                                 Mu
                                                               Kappa
         & Kappa & Lambda & Mu
                                    //
Iota
\bottomrule
\end{booktabs}
```

From version 2022A (2022-03-01), there is a longtabs environment for writing long booktabs tables, and a talltabs environment for writing tall booktabs tables.

5.3 Library counter

You need to load counter library with \UseTblrLibrary{counter}, if you want to modify some LaTeX counters inside tabularray tables.

```
\newcounter{mycnta}
\newcommand{\mycnta}{\stepcounter{mycnta}\arabic{mycnta}}
                                                                                 2
                                                                                     3
                                                                              1
\begin{tblr}{hlines}
  \mycnta & \mycnta & \mycnta \\
                                                                              4
                                                                                 5
                                                                                     6
  \mycnta & \mycnta & \mycnta \\
                                                                              7
                                                                                 8
                                                                                     9
  \mycnta & \mycnta & \mycnta \\
\end{tblr}
```

5.4 Library diagbox

When writing \UseTblrLibrary{diagbox} in the preamble of the document, tabularray package loads diagbox package, and you can use \diagbox and \diagboxthree commands inside tblr environment.

```
\begin{tblr}{hlines, vlines}
                                                                  Ρр
                                                                       Beta
                                                                               Gamma
\diagbox{Aa}{Pp} & Beta & Gamma \\
Epsilon & Zeta & Eta \\
                                                             Epsilon
                                                                       Zeta
                                                                               Eta
        & Kappa & Lambda \\
Iota
                                                             Iota
                                                                       Kappa
                                                                               Lambda
\end{tblr}
                                                             Pp`
                                                                 Hh
\begin{tblr}{hlines, vlines}
                                                                       Beta
                                                                               Gamma
\diagboxthree{Aa}{Pp}{Hh} & Beta & Gamma \\
                                                             Aa
Epsilon & Zeta & Eta \\
                                                             Epsilon
                                                                       Zeta
                                                                               Eta
        & Kappa & Lambda \\
Iota
                                                                       Kappa
                                                                               Lambda
\end{tblr}
                                                             Iota
```

You can also use \diagbox and \diagboxthree commands in math mode.

```
$\begin{tblr}{|c|cc|}
\hline
                                                                              X_2
\diagbox{X_1}{X_2} & 0 & 1 \\
                                                                                   0
                                                                                        1
\hline
                                                                                        0.2
                                                                                   0.1
  0 & 0.1 & 0.2 \\

5.5 Library functional

With \UseTblrLibrary{functional} in the preamble of the document, tabularray will load functional package, and define outer key evaluate and inner key process. These two new keys are useful for doing functional programming inside tables.

5.5.1 Outer key evaluate in action

With outer key evaluate, you can evaluate every occurrence of a specified protected function (defined with \prgNewFunction) and replace it with the return value before splitting the table body.

The first application of evaluate key is for inputting files inside tables. Assume you have two files test1.tmp and test2.tmp with the following contents:

```
\begin{filecontents*}[overwrite]{test1.tmp}
Some & Some \\
\end{filecontents*}
```

```
\begin{filecontents*}[overwrite]{test2.tmp}
Other & Other \\
\end{filecontents*}
```

Then you can input them with outer specification evaluate=\fileInput. The \fileInput function is provided by functional package.

```
\begin{tblr}[evaluate=\fileInput]{hlines}
                                                                          Row1
                                                                                 1
 Row1 & 1 \\
                                                                          Some
                                                                                 Some
  \fileInput{test1.tmp}
                                                                          Row3
                                                                                 3
 Row3 & 3 \\
  \fileInput{test2.tmp}
                                                                          Other
                                                                                 Other
 Row5 & 5 \\
                                                                          Row5
                                                                                 5
\end{tblr}
```

In general, you can define your functions which return parts of table contents, and use evaluate key to evaluate them inside tables.

```
\IgnoreSpacesOn
\prgNewFunction \someFunc {m} {
  \prgReturn {#1 & #1 \\}
                                                                           Row1
                                                                                   1
\IgnoreSpacesOff
                                                                           Text
                                                                                   Text
\begin{tblr}[evaluate=\someFunc]{hlines}
                                                                           Row3
                                                                                   3
 Row1 & 1 \\
                                                                            Text
                                                                                   Text
  \someFunc{Text}
 Row3 & 3 \\
                                                                            Row5
                                                                                   5
 \someFunc{Text}
 Row5 & 5 \\
\end{tblr}
```

```
\IgnoreSpacesOn
\prgNewFunction \otherFunc {} {
  \prgReturn {Other & Other \\}
                                                                          Row1
                                                                                 1
\IgnoreSpacesOff
                                                                          Other
                                                                                 Other
\begin{tblr}[evaluate=\otherFunc]{hlines}
                                                                          Row3
                                                                                 3
 Row1 & 1 \\
                                                                          Other
                                                                                 Other
  \otherFunc
 Row3 & 3 \\
                                                                          Row5
  \otherFunc
 Row5 & 5 \\
\end{tblr}
```

You can even generate the whole table with some function.

```
\IgnoreSpacesOn
\prgNewFunction \makeEmptyTable {mm} {
  \tlSet \lTmpaTl {\intEval{#2-1}} {&}}
  \tlPutRight \lTmpaTl {\\}
  \intReplicate {#1} {\tlUse \lTmpaTl}
}
\IgnoreSpacesOff
\begin{tblr}[evaluate=\makeEmptyTable]{hlines,vlines}
  \makeEmptyTable{3}{7}
\end{tblr}
```

From version 2023A, you can evaluate all functions in the table body with option evaluate=all.

5.5.2 Inner key process in action

With inner key process, you can modify the contents and styles before the table is built. Several public functions defined with \prgNewFuncton are provided for you:

- \cellGetText{<rownum>}{<colnum>}
- \cellSetText{<rownum>}{<colnum>}{<text>}
- \cellSetStyle{<rownum>}{<colnum>}{<style>}
- \rowSetStyle{<rownum>}{<style>}
- \columnSetStyle{<colnum>}{<style>}

As the first example, let's calculate the sums of cells column by column:

```
\IgnoreSpacesOn
\prgNewFunction \funcSum {} {
   \intStepOneInline {1} {\arabic{colcount}}} {
     \intStepOneInline {1} {\arabic{rowcount}-1} {
      \intAdd \lTmpaInt {\cellGetText {####1} {##1}}
   }
   \cellSetText {\expWhole{\arabic{rowcount}}} {##1} {\intUse\lTmpaInt}
}
\IgnoreSpacesOff
```

```
\begin{tblr}{colspec={rrr},process=\funcSum}
\hline
 1 & 2 & 3 \\
                                                                             1
                                                                                 2
                                                                                      3
 4 & 5 & 6 \\
                                                                             4
                                                                                 5
                                                                                      6
 7 & 8 & 9 \\
                                                                                      9
                                                                             7
                                                                                 8
\hline
                                                                            12
                                                                                15
                                                                                     18
   & &
            11
\hline
\end{tblr}
```

Now, let's set background colors of cells depending on their contents:

```
\IgnoreSpacesOn
\prgNewFunction \funcColor {} {
  \intStepOneInline {1} {\arabic{rowcount}} {
    \intStepOneInline {1} {\arabic{colcount}} {
    \intSet \ITmpaInt {\cellGetText {##1} {####1}}
    \intCompareTF {\ITmpaInt} > {0}
        {\cellSetStyle {##1} {####1} {bg=purple8}}
        {\cellSetStyle {##1} {####1} {bg=olive8}}
   }
}
}
IgnoreSpacesOff
```

```
\begin{tblr}{hlines,vlines,cells={r,$},process=\funcColor}
-1 & 2 & 3 \\
4 & 5 & -6 \\
7 & -8 & 9 \\
end{tblr}
```

We can also use color series of xcolor package to color table rows:

```
\definecolor{lightb}{RGB}{217,224,250}
\definecolorseries{tblrow}{rgb}{last}{lightb}{white}
\resetcolorseries[3]{tblrow}
\IgnoreSpacesOn
\prgNewFunction \funcSeries {} {
  \intStepOneInline {1} {\arabic{rowcount}}} {
    \tlSet \lTmpaTl {\intMathMod {##1-1} {3}}
    \rowSetStyle {##1} {\expWhole{bg=tblrow!![\lTmpaTl]}}
}
}
\IgnoreSpacesOff
```

```
\begin{tblr}{hlines,process=\funcSeries}
                                                                            Row1
                                                                                   1
 Row1 & 1 \\
                                                                            Row2
                                                                                   2

                                                                            Row3
                                                                                   3
 Row3 & 3 \\
 Row4 & 4 \\
                                                                            Row4
                                                                                   4
 Row5 & 5 \\
                                                                            Row5
                                                                                   5
 Row6 & 6 \\
                                                                            Row6
                                                                                   6
\end{tblr}
```

5.6 Library nameref

From version 2022D, you can load nameref library to make \nameref and longtblr work together.

5.7 Library siunitx

When writing \UseTblrLibrary{siunitx} in the preamble of the document, tabularray package loads siunitx package, and defines S column as Q column with si key.

```
\begin{tblr}{
  hlines, vlines,
                                                                                                        Head
                                                                                              Head
  colspec={S[table-format=3.2]S[table-format=3.2]}
                                                                                              111
                                                                                                        111
 {\{\{Head\}\}\} \& \{\{\{Head\}\}\} \setminus \{\{\{Head\}\}\}\} \setminus \{\{\{Head\}\}\}\} }
                                                                                                2.1
                                                                                                          2.2
    111 & 111
                                 11
      2.1
               &
                      2.2
                                 11
                                                                                               33.11
                                                                                                         33.22
     33.11 &
                      33.22
                                 11
\end{tblr}
```

```
\begin{tblr}{

    2.1
        &
              2.2
                    11
                                                            33.11
                                                                  33.22
   33.11 &
              33.22 \\
\end{tblr}
```

Note that you need to use <u>triple</u> pairs of curly braces to guard non-numeric cells. But it is cumbersome to enclose each cell with braces. From version 2022B (2022-06-01) a new key guard is provided for cells and rows. With guard key the previous example can be largely simplified.

```
\begin{tblr}{
 hlines, vlines,
  colspec={Q[si={table-format=3.2},c]Q[si={table-format=3.2},c]},
                                                                         Head
                                                                                 Head
  row{1} = {guard}
                                                                         111
                                                                                 111
   Head & Head
                  11
                                                                           2.1
                                                                                   2.2
         & 111
  111
                  11
                                                                                  33.22
                                                                          33.11
    2.1 & 2.2 \\
   33.11 & 33.22 \\
\end{tblr}
```

Also you must use 1, c or r to set horizontal alignment for non-numeric cells:

```
\begin{tblr}{
  hlines, vlines, columns={6em},
  colspec={
    Q[si={table-format=3.2,table-number-alignment=left},1,blue7]
    Q[si={table-format=3.2,table-number-alignment=center},c,teal7]
    Q[si={table-format=3.2,table-number-alignment=right},r,purple7]
  },
  row{1} = {guard}
}
  Head & Head
                 & Head
       & 111
                 & 111
                          11
   2.1 & 2.2 & 2.3 \\
  33.11 & 33.22 & 33.33 \\
\end{tblr}
 Head
                                    Head
                   Head
 111
                  111
                                    111
                    2.2
   2.1
                                     2.3
  33.11
                   33.22
                                    33.33
```

Both S and s columns are supported. In fact, These two columns have been defined as follows:

```
\NewColumnType{S}[1][]{Q[si={#1},c]}
\NewColumnType{s}[1][]{Q[si={#1},c,cmd=\TblrUnit]}
```

You don't need to and are not allowed to define them again.

5.8 Library varwidth

To build a nice table, tabularray need to measure the widths of cells. By default, it uses \hbox to measure the sizes. This causes an error if a cell contains some vertical material, such as lists or display maths.

With \UseTblrLibrary{varwidth} in the preamble of the document, tabularray will load varwidth package, and add a new inner specification measure for tables. After setting measure=vbox, it will use \vbox to measure cell widths.

From version 2022A (2022-03-01), you can remove extra space above and below lists, by adding option stretch=-1. The following example also needs enumitem package and its nosep option:

• List List List List	0000
• List List List List List	
• List List List List	
• List List List List List	gggg

```
\begin{tblr}{
  hlines,vlines,rowspec={Q[1,t]Q[1,b]},
  measure=vbox,stretch=-1,
}
  \begin{itemize} [nosep]
   \item List List List List List
   \item List List List List List
  \end{itemize} & oooo \\
  \begin{itemize} (nosep)
   \item List List List List List
  \item List List List List List
  \item List List List List List
  \end{itemize} & gggg \\
end{tblr}
```

Note that option stretch=-1 also removes struts from cells, therefore it may not work well in tabularray environments with rowsep=0pt, such as booktabs/longtabs/talltabs environments from booktabs library.

5.9 Library zref

From version 2022D, you can load zref library to make \zref and longtblr work together.

Tips and Tricks

6.1 Control Horizontal Alignment

You can control horizontal alignment of cells in tabularray with ragged2e package, by redefining some of the following commands:

```
\RenewDocumentCommand\TblrAlignBoth{}{\justifying}
\RenewDocumentCommand\TblrAlignLeft{}{\RaggedRight}
\RenewDocumentCommand\TblrAlignCenter{}{\Centering}
\RenewDocumentCommand\TblrAlignRight{}{\RaggedLeft}
```

Please read the documentation of ragged2e package for more details of their alignment commands.

6.2 Use Safe Verbatim Commands

Due to the limitation of TeX, even if you have passed verb option to a tabularray table, you still could not use some special characters in a \verb command. As an replacement, you may use \fakeverb command from codehigh package.

The \fakeverb command will remove the backslashes in the following control symbols before typesetting its content: \\, \{, \}, \#, \^ and \ $_{\sqcup}$, \%. Also the argument of \fakeverb command need to be enclosed with curly braces. Therefore it could be safely used inside tabularray tables and other LaTeX commands.

Here is an example of using \fakeverb commands inside a tblr environment (you don't need verb option to use \fakeverb):

```
\begin{tblr}{\nlines}
Special & \fakeverb{\abc{}$&^_\uvw 123} \\
Spacing & \fakeverb{\bfseries\ \#\%} \\
Nesting & \fbox{\fakeverb{\sheft\\\{A\right.$\\#}}}
\end{tblr}

Special \abc{\$$^_\uvw 123}
Spacing \bfseries #%

Nesting \text{Nesting \text{\fakeverb{\sheft\\\{A\right.$\\\#}}}}
\end{tblr}
```

In the above example, balanced curly braces and control words (such as **\bfseries**) need not to be escaped—only several special characters need to be escaped. Please read the documentation of **codehigh** package for more details of **\fakeverb** commands.¹

¹By the way, \EscVerb command from fvextra package is similar to \fakeverb command, but with \EscVerb you need to escape every control word.

History and Future

7.1 The Future

Starting from 2022, except for hotfix releases for critical bugs, every new release will be published on the first day of some month. You may watch the milestones page for the scheduled dates of upcoming releases and their changes:

https://github.com/lvjr/tabularray/milestones

To make the upcoming releases more stable, you are very welcome to test the latest package file in the repository. To test it, you only need to download the following tabularray.sty and put it into the folder of your TeX documents:

https://github.com/lvjr/tabularray/raw/main/tabularray.sty

7.2 The History

The change log of tabularray package will be updated on the wiki page:

https://github.com/lvjr/tabularray/wiki/ChangeLog

In version 2023A, inner key verb was marked as obsolete, and it will be removed in the future. But don't worry too much, because you can stick to old version by \usepackage{tabularray}[=2023-03-01].

In version 2022A, there were several breaking changes:

- \multicolumn command was removed; it is better to use \SetCell command.
- \multirow command was removed; it is better to use \SetCell command.
- \firsthline command was removed; it is better to use baseline=T option.
- \lasthline command was removed; it is better to use baseline=B option.

For your old documents, you can still rollback to version 2021 by \usepackage{tabularray}[=v2021].
